

COMP 722 E-commerce Fall 2007 Programming Assignment 6

Due in the digital drop box by Friday, Nov. 30 at 11:00 PM

1. Write a PHP script to generate a webpage structured so that a significant part of the form data is communicated to the script in two-dimensional arrays. The script fielding the form submission should write the form data to file. Another script should read and display the data. The data should have meaningful fields within the lines. This is a total of three main files, one `.html` file and two `.php` files.
2. Write your own PHP script that uses `include()` to assemble the parts (header, footer, etc.) of a webpage. Include a form with tabular (array) data. Define your own functions to work on this data, and return the results in an HTML document that reuses the header, footer, etc. used in for the first document. This is a total of two `.php` files plus however many include files are needed. In this problem, you should demonstrate your mastery of PHP functions.
